TXV series pumps with Load Sensing control

**ADVANTAGES**

- **TXV series pumps** are variable displacement with pressure-flow control – called *Load Sensing*. They self-regulate to give just the flow required for each movement.

- Specifically designed for the needs of the truck hydraulics market, TXV pumps are particularly well adapted for applications in:
  - loader cranes,
  - forestry cranes,
  - refuse vehicles,
  - salt spreaders, snow and ice equipment,
  - construction equipment vehicles.

- Extremely compact in size to allow direct flange-mounting on vehicle engine or gearbox PTOs.

- TXV pumps are available in 9 models with maximum displacement from 2.44 to 9.15 cu.in/rev (40 to 150 cc/rev).

  Maximum pressure is up to 6092 psi (420 bar) depending on model.
**Why use a variable displacement pump?**

- Installing a TXV variable displacement pump will transform your hydraulic equipment. Slow or rapid movements are done with precision, due to the constant adjustment of pump flow rate.

- The pump incorporates a load sensing device to control flow and maximum pressure. This control device is piloted by a proportional valve which informs the pump of the flow needed for the different circuits supplied by the pump, independently of pressure.

1 & 3

For slow and precise movements, the pump adjusts its flow to whatever the user needs, whilst also controlling maximum circuit pressure. Oil heating and lamination, and noise level, are considerably reduced compared to a fixed displacement pump.

The motor driving the pump only provides the power actually needed by the equipment, thus ensuring:

- longer service life of that equipment;
- significant gains in energy consumption;
- and overall a more environmentally friendly solution.

2

For rapid movements, the pump supplies the required flow virtually instantaneously.
TXV variable displacement pumps are of axial piston design with 11 pistons, thus ensuring optimal regularity of flow and a low noise level.

The displacement of the pump is proportional to the stroke of the pistons. Displacement – and thus flow - is varied by changing the angle $\alpha$ of the swashplate (Fig. 1).

To change displacement from maximum to zero (complete flow cancellation), the swashplate angle goes from $\alpha_{\text{max}}$ (Fig. 1) to $\alpha_{\text{min}} (\approx 0)$ (Fig. 2).

Setting the servo pump.
Pressure-flow regulation: "Load Sensing" - TXV

**Zero flow (standby)**

The proportional valve is closed. The pressure in the P line increases until it reaches the value at which the standby spring is set. Under the pressure in the P line, the spool moves and oil flow supplies the setting piston which moves the swashplate into vertical position \( \alpha = 0 \): no flow, but standby pressure is maintained. The pump stays in standby mode.

**Full flow**

The proportional valve is fully open, allowing passage of pump flow. The pressure in the LS line is the same as in the P line. Hydraulic pressure is the same on either side of the spool. The standby spring holds the spool in its closed position. The cancellation piston is not supplied with oil. The swashplate is at maximum angle \( \alpha \): the pump is at full displacement.

**Flow control**

As soon as the proportional valve tends to reduce the flow requested by the user, the pressure drop created allows the pump displacement setting piston to be piloted. This setting piston automatically adjusts pump displacement to match the order given by the proportional valve.

**Zero flow (maximum pressure)**

This is the case for example of a cylinder which arrives at a mechanical stop. The proportional valve is still open. The pressure of the cylinder at a mechanical stop is sensed by the pump pressure relief valve which opens at the set pressure (PC). This allows the pump displacement setting piston to be supplied and the pump sets itself to a displacement just sufficient to maintain the circuit pressure.
TXV - Characteristics

TXV pumps are available in 9 models from 2.44 to 9.15 cu.in/rev (40 to 150 cc/rev) maximum displacement.

</table>

(1) TXV pumps can be set for smaller maximum displacements (see page 41).
(2) For a mechanical efficiency at 85%.
(3) Higher speed - at full displacement - possible depending on flow required: please contact us.
Viscosity affects maximum possible rotating speed. If viscosity > 400 cSt, please contact us to obtain corresponding speed possibilities.
indexable series: see pages 34 and 35.
(4) Value of the overhang torque of the only pump.

► Calculation of power to be supplied to the shaft as a function of flow and pressure

\[ P = \frac{\Delta P \times Q}{600 \times \eta_{\text{global}}} \]

With:
- \( P \) = Hydraulic power in kW
- \( \Delta P \) = Differential pressure in psi (bar)
- \( Q \) = Flow in l/min
- \( C \) = Torque in lbf ft (N.m)
- \( Cyl \) = Displacement in cc/rev
- \( \eta_{\text{meca}} \) = Mechanical efficiency
- \( \eta_{\text{global}} \) = Mechanical efficiency + volumetric efficiency

Calculation of torque to determine PTO, as a function of the displacement and the pressure

\[ C = \frac{\text{Cyl} \times \Delta P}{62.8 \times \eta_{\text{meca}}} \]

► Ideal installation

► Force on pump shaft

Fr : Acceptable max. radial force = 3000 N
Fa : Acceptable axial force = 1600 N.

The TXV 130 pump exists in a “through shaft” version.

With side porting for inlet and output, this “through shaft” TXV 130 configuration means any LEDUC TXV pump, or fixed displacement XPi or PA pump, can be mounted on the back.

The maximum displacement of the “through shaft” TXV 130 can be factory set, on request, between 3.66 and 7.93 cu.in (60 and 130 cc/rev). It is important to check that maximum torque to be transmitted by the shaft of the “through shaft” TXV 130 does not exceed 664 lbf ft (900 N.m).
Support device

The support device for the pump must be fixed to the same part which the pump is mounted on (see diagram below) and has to be designed to avoid strain on the pump flange.

Maximum torque transferable by the shaft of the pump driven by the PTO:

\[ C = 664 \text{ lbf f (900 N.m)} \]

That is, the sum of torque for both pumps must be less than 664 lbf f (900 N.m).

Please consult our Technical Department for advice regarding your installations.
